

[Aural Analytics](#) builds applications that use speech to detect subtle changes in brain health.

The bar for clinical grade speech analytics has to be high given what's at stake. The V3 framework allows us to provide evidence to ourselves and our customers that our metrics clear that bar.

— **Julie Liss,**
Co-Founder, Aural Analytics

The Problem

- » We developed speech-based measures of cognition that required validation.

The Impact

- ✓ In research, our V3 validated speech measures are being used as endpoints across clinical trials and real-world evidence studies.
- ✓ Digital health companies are using the speech measures to collect real-world evidence in a variety of clinical conditions and we are collaborating to deploy these speech measures as part of clinical care and digital patient engagement programs.

The Resources

- » We used DiMe's [V3 Framework](#) to validate our speech-based measures of cognition.
- » We developed the measure on one dataset and evaluated it on an external database (over 2,000 speech samples) by comparing accuracy against a manually calculated metric (analytical validation) and evaluating its relationship to existing neuropsychological scales (clinical validation).
- » Prior to validating the measure, we verified that the hardware used to acquire the data provided speech samples of sufficient quality for accurate transcription for speech samples collected with supervision in-clinic and independently at-home (verification).
